

Package ‘Manifoldgstat’

July 13, 2019

Type Package

Title Kriging prediction for manifold-valued data.

Version 1.0.0

Description Predictive analysis for manifold-valued data. This package provides a C++ implementation of functions to create a model for spatial dependent manifold-valued data, in order to perform kriging. In each location, specified by a vector of coordinates ([lat,long], [x,y] or [x,y,z]), the datum is supposed to be a symmetric positive definite matrix. The user is provided with three main functions: model_kriging, full_RDD, mixed_RDD, each designed to deliver kriging predictions following the corresponding algorithm (GlobalModel, FullRDD and MixedRDD), as presented in the reference dissertation. They exploit, to different extents, tangent space approximations, Random Domain Decomposition and advanced differential geometry concepts like parallel transport.

Reference Ilaria Sartori Luca Torriani (2019): Mixed Random Domain Decomposition: an innovative approach for kriging prediction of manifold valued data, Master Degree Thesis

Depends R (>= 3.2.0), Rcpp (>= 0.12.16), RcppEigen (>= 0.3.3.4.0), plyr(>= 1.8.4)

assign2center	<i>Assign a point to the cell with the closest center</i>
---------------	---

Description

...

Usage

assign2center(distance.vector)

Arguments

distance.vector
vector of length K containing the distances between the point and the centers

Details

...

Value

it returns the index(es) of the cell(s) with the closest center(s). Returns 0 if the minimum does not exists

bootstrapVar	<i>Compute the bootstrap variance</i>
--------------	---------------------------------------

Description

Compute the bootstrap variance

Usage

```
bootstrapVar(res.boot, res.aggr, K, metric_manifold)
```

Arguments

res.boot	A list of length B. Each field contains a list with the M predictions generated by the corresponding iteration
res.aggr	A list of length M. Each field a single prediction, computed aggregating the corresponding data in res.boot
K	number of cells the domain is subdivided in
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot"

Value

It returns a vector of length M (i.e. the number of locations where we predict), containing the the prediction variance in the corresponding location

create.rdd	<i>Divide the domain in K subregions</i>
------------	--

Description

...

Usage

```
create.rdd(K, method.rdd = "Voronoi", data_coords, graph.distance,
  nk_min, grid, data.grid.distance, suppressMes = T)
```

Arguments

K	number of regions the domain is divided in
method.rdd	method used to define the subregions. So far only "Voronoi" has been implemented
data_coords	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates of the locations where data has been measured
graph.distance	N*N distance matrix (the [i,j] element is the length of the shortest path between points i and j)

nk_min	minimum number of observations within a cell
grid	prediction grid, i.e. $M \times 2$ or $M \times 3$ matrix of coordinates where to predict
data.grid.distance	$N \times M$ distance matrix between locations where the datum has been observed and locations where the datum has to be predicted
suppressMes	{TRUE, FALSE} controls the level of interaction and warnings given

Details

...

Value

it returns a list with the following fields

- assign vector of length N that indicates, for every known location, the cell it has been assigned to
- centers $K \times 3$ matrix reporting the coordinates and the index of the locations drawn as centers of the K cells
- assigng vector of length M that indicates, for every new location, the cell it has been assigned to
- gridk list of K elements. The i -th element contains the coordinates of the grid points assigned to the i -th cell
- graph.distance.grid.centers $K \times M$ matrix containing the distances between each grid points and the K centers

distance_manifold	<i>Distance on the manifold</i>
-------------------	---------------------------------

Description

Compute the manifold distance between symmetric positive definite matrices

Usage

```
distance_manifold(data1, data2, metric_manifold = "Frobenius")
```

Arguments

data1	Either a list/array $[p, p, B1]$ of $B1$ symmetric positive definite matrices of dimension $p \times p$, or a single $p \times p$ matrix
data2	Either a list/array $[p, p, B2]$ of $B2$ symmetric positive definite matrices of dimension $p \times p$, or a single $p \times p$ matrix.
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot", "Correlation"

Details

If $B2=B1$ then the result is a vector of length $B1=B2$ containing in position i the manifold distance between $data1[, , i]$ and $data2[, , i]$. Instead if $B2=1$ and $B1 \neq 1$ the result is a vector of length $B1$ containing in position i the manifold distance between $data1[, , i]$ and $data2[, , 1]$

Value

A vector of distances, or a double if `data1` and `data2` are single matrices.

Examples

```
data_manifold_model <- Manifoldgstat::rCov
distances <- distance_manifold(data_manifold_model, diag(2), metric_manifold = "Frobenius")
print(distances)
```

Eucldist

Compute the Euclidean distance between two points

Description

...

Usage

```
Eucldist(c1, c2)
```

Arguments

<code>c1</code>	coordinates of the first point.
<code>c2</code>	coordinates of the second point.

Details

...

Value

the Euclidean distance between `c1` and `c2`

full_RDD

*Perform full_RDD***Description**

Perform kriging prediction using FullRDD procedure

Usage

```
full_RDD(data_coords, data_val, K, grid, nk_min = 1, B = 100,
  suppressMes = F, tol = 1e-12, max_it = 100, n_h = 15,
  tolerance_intrinsic = 10^(-6), X = NULL, X_new = NULL,
  ker.width.intrinsic = 0, ker.width.vario = 1.5,
  graph.distance.complete, data.grid.distance, aggregation_mean,
  aggregation_kriging, method.analysis = "Local mean", metric_manifold,
  metric_ts, model_ts, vario_model, distance = NULL)
```

Arguments

data_coords	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates. [lat,long] are supposed to be provided in signed decimal degrees
data_val	array [p,p,N] of N symmetric positive definite matrices of dimension p*p
K	number of cells the domain is subdivided in
grid	prediction grid, i.e. M*2 or M*3 matrix of coordinates where to predict
nk_min	minimum number of observations within a cell
B	number of <i>divide</i> iterations to perform
suppressMes	{TRUE, FALSE} controls the level of interaction and warnings given
tol	tolerance for the main loop of model_kriging
max_it	maximum number of iterations for the main loop of model_kriging
n_h	number of bins in the empirical variogram
tolerance_intrinsic	tolerance for the computation of the intrinsic mean
X	matrix (N rows and unrestricted number of columns) of additional covariates for the tangent space model, possibly NULL
X_new	matrix (with the same number of rows of new_coords) of additional covariates for the new locations, possibly NULL
ker.width.intrinsic	parameter controlling the width of the Gaussian kernel for the computation of the local mean (if 0, a "step kernel" is used, giving weight 1 to all the data within the cell and 0 to those outside of it)
ker.width.vario	parameter controlling the width of the Gaussian kernel for the computation of the empirical variogram (if 0, a "step kernel" is used, giving weight 1 to all the data within the cell and 0 to those outside of it)
graph.distance.complete	N*N distance matrix (the [i,j] element is the length of the shortest path between points i and j)

<code>data.grid.distance</code>	N*M distance matrix between locations where the datum has been observed and locations where the datum has to be predicted
<code>aggregation_mean</code>	"Weighted" to aggregate the mean predictions using kernel-based weights, "Equal" to use equal weights
<code>aggregation_kriging</code>	"Weighted" to aggregate the Kriging predictions using kernel-based weights, "Equal" to use equal weights
<code>method.analysis</code>	"Local mean" to predict just with the mean, "Kriging" to predict via Kriging procedure
<code>metric_manifold</code>	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot"
<code>metric_ts</code>	metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"
<code>model_ts</code>	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
<code>vario_model</code>	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
<code>distance</code>	type of distance between coordinates. It must be either "Euclidist" or "Geodist"

Details

It uses a repetition of local analyses, through a *divide et impera* strategy. In the *divide* step, the domain is randomly decomposed in subdomains where local tangent-space models are estimated in order to predict at new locations (in each subregion is performed exactly the analysis described in the `model_kriging` function). This is repeated B times with different partitions of the domain. Then, in the *impera* step, the results of these iterations are aggregated, by means of the intrinsic mean, to provide a final prediction.

Value

According to the analysis chosen:

- If `method.analysis = "Local mean"` it returns a list with the following fields
 - `resBootstrap` A list consisting of
 - * `fmean` list of length B. Each field contains the prediction (at iteration b) for each new location, obtained as the intrinsic mean of the data within the tile it belongs to
 - * `kervalues_mean` Weights used for aggregating `fmean`
 - `resAggregated Predictions`, for each new location, obtained aggregating `fmean` using `kervalues_mean` as weights
- If `method.analysis = "Kriging"` it returns a list with the following fields
 - `resBootstrap` A list consisting of
 - * `fmean` list of length B. Each field contains the prediction (at iteration b) for each new location, obtained as the intrinsic mean of the data within the tile it belongs to
 - * `fpred` list of length B. Each field contains the prediction (at iteration b) for each new location, obtained through kriging
 - * `kervalues_mean` Weights used for aggregating `fmean`

- * kervalues_krig Weights used for aggregating fpred
- * variofit list of length B. Each field contains, for each datum, the parameters of the variogram fitted in the tile it belongs to
- resAggregated Predictions, for each new location, obtained aggregating fpred using kervalues_krig as weights
- resLocalMean Predictions, for each new location, obtained aggregating fmean using kervalues_mean as weights

Geodist

Compute the great-circle distance between two points

Description

...

Usage

Geodist(c1, c2)

Arguments

- | | |
|----|--|
| c1 | coordinates [lat, long] of the first point. |
| c2 | coordinates [lat, long] of the second point. |

Details

The distance is computed using the Haversine formula

Value

the great-circle distance between c1 and c2

intrinsic_mean

Intrinsic mean

Description

Evaluate the intrinsic mean of a given set of symmetric positive definite matrices

Usage

```
intrinsic_mean(data, metric_manifold = "Frobenius",
  metric_ts = "Frobenius", tolerance = 1e-06,
  weight_intrinsic = NULL, weight_extrinsic = weight_intrinsic,
  tolerance_map_cor = 1e-06)
```

Arguments

data	list or array [p,p,B] of B symmetric positive definite matrices of dimension p*p
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot", "Correlation"
metric_ts	metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"
tolerance	tolerance for the computation of the intrinsic mean
weight_intrinsic	vector of length B to weight the matrices in the computation of the intrinsic mean. If NULL a vector of ones is used
weight_extrinsic	vector of length B to weight the matrices in the computation of the extrinsic mean. If NULL weight_intrinsic is used
tolerance_map_cor	tolerance to use in the maps. Required only if metric_manifold== "Correlation"

Value

A matrix representing the intrinsic mean of the data

References

X. Pennec, P. Fillard, and N. Ayache. A riemannian framework for tensor computing. International Journal of computer vision, 66(1):41-66, 2006.

Examples

```
data_manifold_tot <- Manifoldgstat::fieldCov
Sigma <-intrinsic_mean(data_manifold_tot, metric_manifold = "Frobenius",
                      metric_ts = "Frobenius")
print(Sigma)
```

kerfn	<i>Evaluate a gaussian kernel</i>
-------	-----------------------------------

Description

...

Usage

```
kerfn(newdata, center, ker.type = "Gau", param)
```

Arguments

newdata	coordinates of the locations where we want to compute the kernel values
center	coordinates of the reference center for the kernel
ker.type	type of kernel. So far only "Gau" (i.e gaussian kernel) has been implemented
param	parameters that define the kernel. For the gaussian kernel it is the sigma parameter

Details

...

Value

the values of the kernel function corresponding to the vector of Euclidean distances between newdata and the center

kriging	<i>Kriging prediction given the model</i>
---------	---

Description

Given the GLS model, kriging prediction on new location(s) is performed.

Usage

```
kriging(GLS_model, coords, new_coords, model_ts = "Additive",
        vario_model = "Gaussian", metric_manifold = "Frobenius",
        X_new = NULL, distance = "Geodist", tolerance_map_cor = 1e-06)
```

Arguments

GLS_model	the object returned by model_GLS, or a list containing the fields: Sigma (tangent point), beta (vector of the beta matrices of the fitted model), gamma_matrix (N*N covariogram matrix), residuals (vector of the N residual matrices), fitted_par_vario (estimates of <i>nugget</i> , <i>sill-nugget</i> and <i>practical range</i>)
coords	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates. [lat,long] are supposed to be provided in signed decimal degrees
new_coords	matrix of coordinates for the M new locations where to perform kriging
model_ts	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
vario_model	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot", "Correlation"
X_new	matrix (with the same number of rows of new_coords) of additional covariates for the new locations, possibly NULL
distance	type of distance between coordinates. It must be either "Eucldist" or "Geodist"
tolerance_map_cor	tolerance to use in the maps. Required only if metric_manifold=="Correlation"
data_grid_dist_mat	Matrix of dimension N*M of distances between data points and grid points. If not provided it is computed using distance

Details

The model provided is used to perform simple kriging on the tangent space in correspondence of the new locations. The estimates are then mapped to the manifold to produce the actual prediction.

Value

A list with a single field:

`prediction` vector of matrices predicted at the new locations

               radius=radius, center.cex=.5, col='red')}
rect(x.min, y.min, x.max, y.max)

```

mixed_RDD

Perform mixed_RDD

Description

Perform kriging prediction using MixedRDD procedure

Usage

```

mixed_RDD(data_coords, data_val, K, grid, nk_min = 1, B = 100,
  suppressMes = F, ker.width.intrinsic = 0, graph.distance.complete,
  data.grid.distance, N_samples, aggregation_mean, metric_ts,
  tol = 1e-12, max_it = 100, n_h = 15,
  tolerance_intrinsic = 10^(-6), max_sill = NULL, max_a = NULL,
  X = NULL, X_new = NULL, create_pdf_vario = FALSE,
  pdf_parameters = NULL, metric_manifold, model_ts, vario_model,
  distance)

```

Arguments

data_coords	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates. [lat,long] are supposed to be provided in signed decimal degrees
data_val	array [p,p,N] of N symmetric positive definite matrices of dimension p*p
K	number of cells the domain is subdivided in
grid	prediction grid, i.e. M*2 or M*3 matrix of coordinates where to predict
nk_min	minimum number of observations within a cell
B	number of <i>divide</i> iterations to perform
suppressMes	{TRUE, FALSE} controls the level of interaction and warnings given
ker.width.intrinsic	parameter controlling the width of the Gaussian kernel for the computation of the local mean (if 0, a "step kernel" is used, giving weight 1 to all the data within the cell and 0 to those outside of it)
graph.distance.complete	N*N distance matrix (the [i,j] element is the length of the shortest path between points i and j)

data.grid.distance	N*M distance matrix between locations where the datum has been observed and locations where the datum has to be predicted
N_samples	number of data N
aggregation_mean	"Weighted" to aggregate the mean predictions using kernel-based weights, "Equal" to use equal weights
metric_ts	metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"
tol	tolerance for the main loop of model_kriging
max_it	maximum number of iterations for the main loop of model_kriging
n_h	number of bins in the empirical variogram
tolerance_intrinsic	tolerance for the computation of the intrinsic mean
max_sill	max value allowed for sill in the fitted variogram. If NULL it is defined as $1.15 \times \max(\text{emp_vario_values})$
max_a	maximum value for a in the fitted variogram. If NULL it is defined as $1.15 \times h_{\max}$
X	matrix (N rows and unrestricted number of columns) of additional covariates for the tangent space model, possibly NULL
X_new	matrix (with the same number of rows of new_coords) of additional covariates for the new locations, possibly NULL
create_pdf_vario	boolean. If TRUE the empirical and fitted variograms are plotted in a pdf file
pdf_parameters	list with the fields test_nr and sample_draw. Additional parameters to name the pdf
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot"
model_ts	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
vario_model	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
distance	type of distance between coordinates. It must be either "Eucldist" or "Geodist"

Details

It employs a *divide et impera* strategy to provide an estimate of a "fictional" field of tangent points, used to encode the information regarding the drift of the field. To this end in the *divide* step, the domain is randomly decomposed and in each subdomain a tangent point (assigned to each location in that subregion) is estimated as the intrinsic mean of the data belonging to it. This is repeated B times with different partitions of the domain and the results are then aggregated in the *impera* stage by means of the intrinsic mean. Eventually, exploiting this "fictional" field of tangent points and the concept of parallel transport, a kriging analysis over the whole domain is performed to predict the field values at new locations.

Value

it returns a list with the following fields

- `resBootstrap` list of length `B`. Each field contains a tangent point estimate (at iteration `b`) for each new location, obtained as the intrinsic mean of the data within the tile it belongs to
- `resAggregated` field of tangent points computed, for each location (both those where data are measured and where they must be predicted), aggregating the corresponding `resBootstrap`
- `model_pred` list with the details of the global model fitted on the common Hilbert space and the resulting kriging predictions. Namely it contains the following fields: `beta` vector of the beta matrices of the fitted model `gamma_matrix` $N \times N$ covariogram matrix `residuals` vector of the `N` residual matrices `emp_vario_values` vector of empirical variogram values in correspondence of `h_vec` `h_vec` vector of positions at which the empirical variogram is computed `fitted_par_vario` estimates of *nugget*, *sill-nugget* and *practical range* iterations number of iterations of the main loop prediction vector of matrices predicted at the new locations

model_GLS	Create a GLS model
-----------	--------------------

Description

Given the coordinates and corresponding manifold values, this function creates a GLS model on the tangent space.

Usage

```
model_GLS(data_manifold, coords, X = NULL, Sigma = NULL,
  metric_manifold = "Frobenius", metric_ts = "Frobenius",
  model_ts = "Additive", vario_model = "Gaussian", n_h = 15,
  distance = "Geodist", max_it = 100, tolerance = 1e-06,
  weight_intrinsic = NULL, tolerance_intrinsic = 1e-06,
  max_sill = NULL, max_a = NULL, param_weighted_vario = NULL,
  plot = FALSE, suppressMes = FALSE, weight_extrinsic = NULL,
  tolerance_map_cor = 1e-06)
```

Arguments

<code>data_manifold</code>	list or array $[p, p, N]$ of N symmetric positive definite matrices of dimension $p \times p$
<code>coords</code>	$N \times 2$ or $N \times 3$ matrix of $[\text{lat}, \text{long}]$, $[x, y]$ or $[x, y, z]$ coordinates. $[\text{lat}, \text{long}]$ are supposed to be provided in signed decimal degrees
<code>X</code>	matrix (N rows and unrestricted number of columns) of additional covariates for the tangent space model, possibly <code>NULL</code>
<code>Sigma</code>	$p \times p$ matrix representing the tangent point. If <code>NULL</code> the tangent point is computed as the intrinsic mean of <code>data_manifold</code>
<code>metric_manifold</code>	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot", "Correlation"
<code>metric_ts</code>	metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"

model_ts	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
vario_model	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
n_h	number of bins in the empirical variogram
distance	type of distance between coordinates. It must be either "Eucldist" or "Geodist"
max_it	max number of iterations for the main loop
tolerance	tolerance for the main loop
weight_intrinsic	vector of length N to weight the locations in the computation of the intrinsic mean. If NULL a vector of ones is used. Not needed if Sigma is provided
tolerance_intrinsic	tolerance for the computation of the intrinsic mean. Not needed if Sigma is provided
max_sill	max value allowed for <i>sill</i> in the fitted variogram. If NULL it is defined as $1.15 \times \max(\text{emp_vario_values})$
max_a	maximum value for <i>a</i> in the fitted variogram. If NULL it is defined as $1.15 \times h_{\max}$
param_weighted_vario	List of 7 elements to be provided to consider Kernel weights for the variogram (significant only within an RDD procedure). Indeed in this case the N_tot data regarding the whole domain must be provided to the algorithm, not only the N in the cell under consideration. Therefore the list must contain the following fields: weight_vario (vector of length N_tot to weight the locations in the computation of the empirical variogram), distance_matrix_tot (N_tot*N_tot matrix of distances between the locations), data_manifold_tot (list or array [p,p,N_tot] of N_tot symmetric positive definite matrices of dimension p*p), coords_tot (N_tot*2 or N_tot*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates), X_tot (matrix with N_tot rows and unrestricted number of columns of additional covariates for the tangent space model, possibly NULL), h_max (maximum value of distance for which the variogram is computed), indexes_model (indexes of the N_tot data corresponding to the N data in the cell).
plot	boolean. If TRUE the empirical and fitted variograms are plotted
suppressMes	boolean. If TRUE warning messages are not printed
weight_extrinsic	vector of length N to weight the locations in the computation of the extrinsic mean. If NULL weight_intrinsic are used. Needed only if Sigma is not provided and metric_manifold== "Correlation"
tolerance_map_cor	tolerance to use in the maps. Required only if metric_manifold== "Correlation"
data_dist_mat	Matrix of dimension N*N of distances between data points. If not provided it is computed using distance

Details

The manifold values are mapped on the tangent space and then a GLS model is fitted to them. A first estimate of the beta coefficients is obtained assuming spatially uncorrelated errors. Then, in the main the loop, new estimates of the beta are obtained as a result of a weighted least square problem where the weight matrix is the inverse of gamma_matrix. The residuals

(`residuals = data_ts - fitted`) are updated accordingly. The parameters of the variogram fitted to the residuals (and used in the evaluation of the `gamma_matrix`) are computed using Gauss-Newton with backtrack method to solve the associated non-linear least square problem. The stopping criteria is based on the absolute value of the variogram residuals' norm if `ker.width.vario=0`, while it is based on its increment otherwise.

Value

A list with the following fields:

<code>beta</code>	vector of the beta matrices of the fitted model
<code>gamma_matrix</code>	N*N covariogram matrix
<code>residuals</code>	vector of the N residual matrices
<code>emp_vario_values</code>	vector of empirical variogram values in correspondence of <code>h_vec</code>
<code>h_vec</code>	vector of positions at which the empirical variogram is computed
<code>fitted_par_vario</code>	estimates of <i>nugget</i> , <i>sill-nugget</i> and <i>practical range</i>
<code>iterations</code>	number of iterations of the main loop
<code>Sigma</code>	tangent point

Examples

```
data_manifold_model <- Manifoldgstat::rCov
coords_model <- Manifoldgstat::rGrid
Sigma <- matrix(c(2,1,1,1), 2,2)
model = model_GLS(data_manifold = data_manifold_model, coords = coords_model, Sigma = Sigma,
  metric_manifold = "Frobenius", metric_ts = "Frobenius", model_ts = "Coord1",
  vario_model = "Spherical", n_h = 15, distance = "EuclDist", max_it = 100,
  tolerance = 1e-7, plot = TRUE)
```

model_kriging

Create a GLS model and directly perform kriging

Description

Given the coordinates and corresponding manifold values, this function firstly creates a GLS model on the tangent space, and then performs kriging on the new locations.

Usage

```
model_kriging(data_manifold, coords, X = NULL, Sigma = NULL,
  metric_manifold = "Frobenius", metric_ts = "Frobenius",
  model_ts = "Additive", vario_model = "Gaussian", n_h = 15,
  distance = NULL, data_dist_mat = NULL, data_grid_dist_mat = NULL,
  max_it = 100, tolerance = 1e-06, weight_intrinsic = NULL,
  tolerance_intrinsic = 1e-06, max_sill = NULL, max_a = NULL,
  param_weighted_vario = NULL, new_coords, X_new = NULL,
  create_pdf_vario = TRUE, pdf_parameters = NULL,
  suppressMes = FALSE, weight_extrinsic = NULL,
  tolerance_map_cor = 1e-06)
```

Arguments

<code>data_manifold</code>	list or array [p,p,N] of N symmetric positive definite matrices of dimension p*p
<code>coords</code>	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates. [lat,long] are supposed to be provided in signed decimal degrees
<code>X</code>	matrix (N rows and unrestricted number of columns) of additional covariates for the tangent space model, possibly NULL
<code>Sigma</code>	p*p matrix representing the tangent point. If NULL the tangent point is computed as the intrinsic mean of <code>data_manifold</code>
<code>metric_manifold</code>	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot", "Correlation"
<code>metric_ts</code>	metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"
<code>model_ts</code>	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
<code>vario_model</code>	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
<code>n_h</code>	number of bins in the empirical variogram
<code>distance</code>	type of distance between coordinates. It must be either "Eucldist" or "Geodist"
<code>data_dist_mat</code>	Matrix of dimension N*N of distances between data points. If not provided it is computed using distance
<code>data_grid_dist_mat</code>	Matrix of dimension N*M of distances between data points and grid points. If not provided it is computed using distance
<code>max_it</code>	max number of iterations for the main loop
<code>tolerance</code>	tolerance for the main loop
<code>weight_intrinsic</code>	vector of length N to weight the locations in the computation of the intrinsic mean. If NULL a vector of ones is used. Not needed if Sigma is provided
<code>tolerance_intrinsic</code>	tolerance for the computation of the intrinsic mean. Not needed if Sigma is provided
<code>max_sill</code>	max value allowed for sill in the fitted variogram. If NULL it is defined as $1.15 \times \max(\text{emp_vario_values})$

max_a	maximum value for a in the fitted variogram. If NULL it is defined as $1.15 \cdot h_{\max}$
param_weighted_vario	List of 7 elements to be provided to consider Kernel weights for the variogram (significant only within an RDD procedure). Indeed in this case the N_{tot} data regarding the whole domain must be provided to the algorithm, not only the N in the cell under consideration. Therefore the list must contain the following fields: weight_vario (vector of length N_{tot} to weight the locations in the computation of the empirical variogram), distance_matrix_tot ($N_{\text{tot}} \times N_{\text{tot}}$ matrix of distances between the locations), data_manifold_tot (list or array [p,p, N_{tot}] of N_{tot} symmetric positive definite matrices of dimension $p \times p$), coords_tot ($N_{\text{tot}} \times 2$ or $N_{\text{tot}} \times 3$ matrix of [lat,long], [x,y] or [x,y,z] coordinates), X_tot (matrix with N_{tot} rows and unrestricted number of columns of additional covariates for the tangent space model, possibly NULL), h_max (maximum value of distance for which the variogram is computed), indexes_model (indexes of the N_{tot} data corresponding to the N data in the cell).
new_coords	matrix of coordinates for the M new locations where to perform kriging
X_new	matrix (with the same number of rows of new_coords) of additional covariates for the new locations, possibly NULL
create_pdf_vario	boolean. If TRUE the empirical and fitted variograms are plotted in a pdf file
pdf_parameters	list with the fields test_nr and sample_draw. Additional parameters to name the pdf
suppressMes	boolean. If TRUE warning messages are not printed
weight_extrinsic	vector of length N to weight the locations in the computation of the extrinsic mean. If NULL weight_intrinsic are used. Needed only if Sigma is not provided and metric_manifold== "Correlation"
tolerance_map_cor	tolerance to use in the maps. Required only if metric_manifold== "Correlation"

Details

The manifold values are mapped on the tangent space and then a GLS model is fitted to them. A first estimate of the beta coefficients is obtained assuming spatially uncorrelated errors. Then, in the main the loop, new estimates of the beta are obtained as a result of a weighted least square problem where the weight matrix is the inverse of gamma_matrix. The residuals ($\text{residuals} = \text{data_ts} - \text{fitted}$) are updated accordingly. The parameters of the variogram fitted to the residuals (and used in the evaluation of the gamma_matrix) are computed using Gauss-Newton with backtrack method to solve the associated non-linear least square problem. The stopping criteria is based on the absolute value of the variogram residuals' norm if `ker.width.vario=0`, while it is based on its increment otherwise. Once the model is computed, simple kriging on the tangent space is performed in correspondence of the new locations and eventually the estimates are mapped to the manifold.

Value

list with the following fields:

beta	vector of the beta matrices of the fitted model
gamma_matrix	$N \times N$ covariogram matrix

residuals	vector of the N residual matrices
emp_vario_values	vector of empirical variogram values in correspondence of h_vec
h_vec	vector of positions at which the empirical variogram is computed
fitted_par_vario	estimates of <i>nugget</i> , <i>sill-nugget</i> and <i>practical range</i>
iterations	number of iterations of the main loop
Sigma	tangent point
prediction	vector of matrices predicted at the new locations

```

model_kriging_mixed *Perform main routine for mixed_RDD*

Description

...

Usage

```

model_kriging_mixed(data_manifold, coords, X = NULL, Sigma_data,
  metric_manifold = "Frobenius", model_ts = "Additive",
  vario_model = "Gaussian", n_h = 15, distance = NULL,
  data_dist_mat = NULL, data_grid_dist_mat = NULL, max_it = 100,
  tolerance = 1e-06, max_sill = NULL, max_a = NULL, new_coords,
  Sigma_new, X_new = NULL, create_pdf_vario = TRUE,
  pdf_parameters = NULL, suppressMes = FALSE)

```

Arguments

data_manifold	array [p,p,N] of N symmetric positive definite matrices of dimension p*p
coords	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates.
X	matrix (N rows and unrestricted number of columns) of additional covariates for the tangent space model, possibly NULL
Sigma_data	List of the N fictional tangent points in correspondence with the data used to build the model
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot"
model_ts	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
vario_model	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
n_h	number of bins in the empirical variogram

distance	type of distance between coordinates. It must be either "Eucldist" or "Geodist"
data_dist_mat	N*N distance matrix (the [i,j] element is the length of the shortest path between points i and j)
data_grid_dist_mat	N*M distance matrix between locations where the datum has been observed and locations where the datum has to be predicted
max_it	maximum number of iterations for the main loop of model_kriging
tolerance	tolerance for the main loop of model_kriging
max_sill	max value allowed for sill in the fitted variogram. If NULL it is defined as $1.15 \cdot \max(\text{emp_vario_values})$
max_a	maximum value for a in the fitted variogram. If NULL it is defined as $1.15 \cdot h_{\max}$
new_coords	prediction grid, i.e. M*2 or M*3 matrix of coordinates where to predict
Sigma_new	List of the M fictional tangent points in correspondence with the locations where we want to predict
X_new	matrix (with the same number of rows of new_coords) of additional covariates for the new locations, possibly NULL
create_pdf_vario	boolean. If TRUE the empirical and fitted variograms are plotted in a pdf file
pdf_parameters	list with the fields test_nr and sample_draw. Additional parameters to name the pdf
suppressMes	{TRUE, FALSE} controls the level of interaction and warnings given

Details

...

Value

it returns a list with the following fields

beta	vector of the beta matrices of the fitted model
gamma_matrix	N*N covariogram matrix
residuals	vector of the N residual matrices
emp_vario_values	vector of empirical variogram values in correspondence of h_vec
h_vec	vector of positions at which the empirical variogram is computed
fitted_par_vario	estimates of <i>nugget</i> , <i>sill-nugget</i> and <i>practical range</i>
iterations	number of iterations of the main loop
prediction	vector of matrices predicted at the new locations

plot_ker_rect	<i>Plot kernel</i>
---------------	--------------------

Description

Plot kernel

Usage

```
plot_ker_rect(data_coords, id, xmax, ymax, m, n, ker.width)
```

Arguments

data_coords	coordinates of the data
id	the index of the row of data_coords that will be used as center
xmax	the maximum value for the x-coordinate (the minimum is 0)
ymax	the maximum value for the y-coordinate (the minimum is 0)
m	number of points on the grid in horizontal direction
n	number of points on the grid in vertical direction
ker.width	kernel width

plot_variogram	<i>Plot empirical and fitted variogram</i>
----------------	--

Description

Plot empirical and fitted variogram

Usage

```
plot_variogram(empirical_variogram, fitted_variogram, model, distance)
```

Arguments

empirical_variogram	A list containing the two following fields: - h_vec: vector of positions at which the empirical variogram is computed - emp_vario_values: vector of empirical variogram values in correspondence of h_vec
fitted_variogram	A list containing the two following fields: - hh: dense vector of positions at which fit_vario_values is computed - fit_vario_values: Vector of fitted variogram values in correspondence of hh
model	Type of variogram used for fitting (it will be reported on the y-axis). It can be "Gaussian", "Spherical" or "Exponential"
distance	Type of distance used to compute h_vec (it will be reported on the x-axis). It must be either "Eucldist" or "Geodist"

RDD_OOK_aggr_man

Aggregate the results of the bootstrap iterations

Description

...

Usage

```
RDD_OOK_aggr_man(fOKBV, weights_intrinsic, ker.width.intrinsic)
```

Arguments

fOKBV list of length B, containing the results obtained, for each location, at the B bootstrap iterations (Usually it is the fmean or fpred returned by RDD_OOK_boot_man or RDD_OOK_boot_man_mixed)

weights_intrinsic weights to use to aggregate the results

ker.width.intrinsic width of the kernel used to compute weights_intrinsic. 0 if we use equal weights

Details

If `ker.width.intrinsic!=0` the data are aggregated using the normalized `weights_intrinsic`. Otherwise equal weights are used

Value

the aggregated result, obtained as the `intrinsic_mean` of `fOKBV`

RDD_OOK_boot_man

Main routine for full_RDD

Description

...

Usage

```
RDD_OOK_boot_man(data_coords, data_val, K, grid, nk_min, B, suppressMes,
  tol, max_it, n_h, tolerance_intrinsic, X, X_new, ker.width.intrinsic,
  ker.width.vario, graph.distance.complete, data.grid.distance,
  method.analysis, metric_manifold, metric_ts, model_ts, vario_model,
  distance)
```

Arguments

<code>data_coords</code>	N*2 or N*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates.
<code>data_val</code>	list of N symmetric positive definite matrices of dimension p*p
<code>K</code>	Number of neighborhood (i.e., centers) to sample at each iteration
<code>grid</code>	M*2 or M*3 matrix of [lat,long], [x,y] or [x,y,z] coordinates of the new locations where to predict
<code>nk_min</code>	Minimum number of observations within a neighborhood
<code>B</code>	Number of bootstrap iterations
<code>suppressMes</code>	boolean. If TRUE warning messages are not printed
<code>tol</code>	tolerance for each main loop
<code>max_it</code>	max number of iterations for each main loop
<code>n_h</code>	number of bins in the empirical variogram
<code>tolerance_intrinsic</code>	tolerance for the computation of the intrinsic mean
<code>X</code>	Additional covariates for the locations used to create the model
<code>X_new</code>	Additional covariates for the M locations where to perform kriging
<code>ker.width.intrinsic</code>	Parameter controlling the width of the Gaussian kernel for the computation of the local mean (if 0, no kernel is used)
<code>ker.width.vario</code>	Parameter controlling the width of the Gaussian kernel for the computation of the empirical variogram (if 0, no kernel is used)
<code>graph.distance.complete</code>	N*N distance matrix (the [i,j] element is the length of the shortest path between points i and j)
<code>data.grid.distance</code>	N*M distance matrix between locations where the datum has been observed and locations where the datum has to be predicted
<code>method.analysis</code>	"Local mean" to predict just with the mean, "Kriging" to predict via Kriging procedure
<code>metric_manifold</code>	Metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot" and "Correlation"
<code>metric_ts</code>	Metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"
<code>model_ts</code>	Type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
<code>vario_model</code>	Type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
<code>distance</code>	Type of distance between coordinates. It must be either "Euclidist" or "Geodist"

Details

...

Value

According to the analysis chosen:

- If `method.analysis = "Local mean"` it returns a list with the following fields
 - `fmean` list of length `B`. Each field contains the prediction (at iteration `b`) for each new location, obtained as the intrinsic mean of the data within the tile it belongs to
 - `kervalues_mean` Weights used for aggregating `fmean`
- If `method.analysis = "Kriging"` it returns a list with the following fields
 - `fmean` list of length `B`. Each field contains the prediction (at iteration `b`) for each new location, obtained as the intrinsic mean of the data within the tile it belongs to
 - `fpred` list of length `B`. Each field contains the prediction (at iteration `b`) for each new location, obtained through kriging
 - `kervalues_mean` Weights used for aggregating `fmean`
 - `kervalues_krig` Weights used for aggregating `fpred`
 - `variofit` list of length `B`. Each field contains, for each datum, the parameters of the variogram fitted in the tile it belongs to

RDD_OOK_boot_man_mixed

Main routine for mixed_RDD

Description

...

Usage

```
RDD_OOK_boot_man_mixed(data_coords, data_val, K, grid, nk_min, B,
  suppressMes, ker.width.intrinsic, graph.distance.complete,
  data.grid.distance, metric_ts, vario_model, tol, max_it, n_h,
  tolerance_intrinsic, X, X_new, metric_manifold, model_ts, distance)
```

Arguments

<code>data_coords</code>	<code>N*2</code> or <code>N*3</code> matrix of <code>[lat,long]</code> , <code>[x,y]</code> or <code>[x,y,z]</code> coordinates. <code>[lat,long]</code> are supposed to be provided in signed decimal degrees
<code>data_val</code>	array <code>[p,p,N]</code> of <code>N</code> symmetric positive definite matrices of dimension <code>p*p</code>
<code>K</code>	number of cells the domain is subdivided in
<code>grid</code>	prediction grid, i.e. <code>M*2</code> or <code>M*3</code> matrix of coordinates where to predict
<code>nk_min</code>	minimum number of observations within a cell
<code>B</code>	number of <i>divide</i> iterations to perform
<code>suppressMes</code>	<code>{TRUE, FALSE}</code> controls the level of interaction and warnings given
<code>ker.width.intrinsic</code>	parameter controlling the width of the Gaussian kernel for the computation of the local mean (if 0, a "step kernel" is used, giving weight 1 to all the data within the cell and 0 to those outside of it)

graph.distance.complete	N*N distance matrix (the [i,j] element is the length of the shortest path between points i and j)
data.grid.distance	N*M distance matrix between locations where the datum has been observed and locations where the datum has to be predicted
metric_ts	metric used on the tangent space. It must be chosen among "Frobenius", "FrobeniusScaled", "Correlation"
vario_model	type of variogram fitted. It must be chosen among "Gaussian", "Spherical", "Exponential"
tol	tolerance for the main loop of model_kriging
max_it	maximum number of iterations for the main loop of model_kriging
n_h	number of bins in the empirical variogram
tolerance_intrinsic	tolerance for the computation of the intrinsic mean
X	matrix (N rows and unrestricted number of columns) of additional covariates for the tangent space model, possibly NULL
X_new	matrix (with the same number of rows of new_coords) of additional covariates for the new locations, possibly NULL
metric_manifold	metric used on the manifold. It must be chosen among "Frobenius", "LogEuclidean", "SquareRoot"
model_ts	type of model fitted on the tangent space. It must be chosen among "Intercept", "Coord1", "Coord2", "Additive"
distance	type of distance between coordinates. It must be either "Eucldist" or "Geodist"

Details

...

Value

it returns a list with the following fields

- fmean list of length B. Each field contains the prediction (at iteration b) for each location, obtained as the intrinsic mean of the data within the tile it belongs to
- kervalues_mean Weights used for aggregating fmean

return_ith_list_element

Return a given element of a list

Description

Return a given element of a list

Usage

```
return_ith_list_element(lista, i)
```

Arguments

lista	A list
i	The index of the element to extract

Value

It returns the i-th element of lista

return_ith_row	<i>Return a given row of a matrix</i>
----------------	---------------------------------------

Description

Return a given row of a matrix

Usage

```
return_ith_row(mat, i)
```

Arguments

mat	A matrix
i	The index of the row to extract

Value

It returns the i-th row of mat
